Abstract

The document describes the fishing activities of the French purse seiners targeting tropical tunas, i.e. *Thunnus albacares*, *Katsuwonus pelamis*, and *Thunnus obesus* in the Indian Ocean during 1991-2009. The catch time series of the fleet over the period 2001-2009 has been updated following a change in the spatial stratification used in the multispecies sampling and a few modifications in data processing. Information is provided on fishing effort (fishing days, searching days, and fishing sets), catch, catch rates, and mean weights for the major tropical tuna species. Two major fishing modes are considered for the fishery: log-associated and free swimming schools,

Keywords: purse seine fishing, *Thunnus albacares*, *Katsuwonus pelamis*, *Thunnus obesus*, fishing aggregating device

1. Introduction

The French purse seine fishing fleet has been monitored by the Institut de Recherche pour le Développement (IRD) in collaboration with the Seychelles Fishing Authority (SFA) since the beginning of the fishery in the early 1980s (Pianet 1999). Since 2002, statistical data from the European fleet (i.e., France and Spain) have been collected within the framework of the EU "Data Collection Regulation" (DCR, Reg. 1543/2000 and 1639/2001), followed in 2008 by the "Community framework for the collection, management and use of data in the fisheries sector and support for scientific advice regarding the Common Fisheries Policy" (DCF, Reg 199/2008 and 665/2008). The document describes the activities of the French purse seine fleet during 1991-2009 that is a time period fully consistent in terms of multispecies sampling scheme and data processing used to correct for the species composition of the catch. Statistical data over the period 1981-1990 can be found in Pianet

---

et al. (2006). The French fleet includes the vessels flying French flags as well as the vessels from the French overseas collectivity of Mayotte. The document provides a new time series of catch data by species since some changes have recently been made in the data processing, particularly through the addition of a spatial stratum so as to take into account the spatial gradients in tuna species composition observed in the Somali area in the 2000s.

2. Changes in data processing

The catch time series of the French purse seine fishing fleet in the Indian Ocean during 2001-2008 has been modified compared to the data available in Pianet et al. (2009). In particular, the progressive expansion of the purse seiners north of the Somali area in the 2000s has revealed significant differences in the species composition of tunas caught in the ET area 'East Somali' (2201) (Pallarés and Hallier 1997), i.e. a strong decrease in bigeye tuna proportion north of 8°N. Accordingly, a change in the spatial strata used to estimate the species composition of tunas based on multispecies sampling has been done through the splitting of the North Somali area stratum into two areas, a 'South Somali' (2201) area comprised between 0 and 8°N and a 'North Somali' area (2211) between 8° and 15°N. The 'Arabian Sea' area (2207) has then been reduced by moving up its southern limit to 15°N. This change did not affect the total catch declarations but only slightly modified the species composition of the catch in the somali area during 2001-2009.

In addition, a few changes have been made over time in the data processing used to correct the species composition of the catch through port sampling (Pallarés and Hallier 1997, Pianet et al. 2000). In particular, a change has been done in March 2002 in the key used to convert dorsal length into fork length data for yellowfin tuna. In November 2003, the substitution scheme of the data processing has been modified. From this period, multi-species port samples from the first 3 substitution levels have been subsequently cumulated to increase sample size, i.e. if the addition of the samples from the first substitution level to the samples from the stratum of interest was not sufficient to reach a target number (e.g. 25 samples), samples from the second substitution level would then be added up to the samples from the first substitution level. Samples from the third substitution level would then be used if necessary. Such modifications have been included to account for progressive improvements in ancillary information provided to the data processing (e.g. morphometric relationships) or in situations of very poor sampling and had only little impact on the time series of catch and effort annually provided to the IOTC.

3. Fishing capacity

The number of fishing vessels of the French purse seine fishing fleet has varied around 16.6 (SD ± 1.3) over the period 1991-2009, with a minimum of 14 and a maximum of 19 in 2003 and 1997, respectively (Fig. 1 and Table 1). The total carrying capacity expressed in

gross tonnage (GRT) has increased through time from about 14,000 t in the early 1980s to more than 16,000 t in the late 2000s (Fig. 1). In summer 2009, 5 vessels left the Indian Ocean toward the Atlantic Ocean, decreasing the total carrying capacity to about 11,000 t. This departure was mainly related to low catch rates compared to the Atlantic ocean and the increasing expansion of Somali piracy attacks that induced a strong reduction of the fishing grounds, particularly in the vicinity of the somali area during the FAD-fishing season (June-October). In September 2009, a new purse seiner, the Franche Terre, entered the fishery. In November 2009, the Torre Giulia which was formerly flying the Italian flag joined the French purse seine fleet.
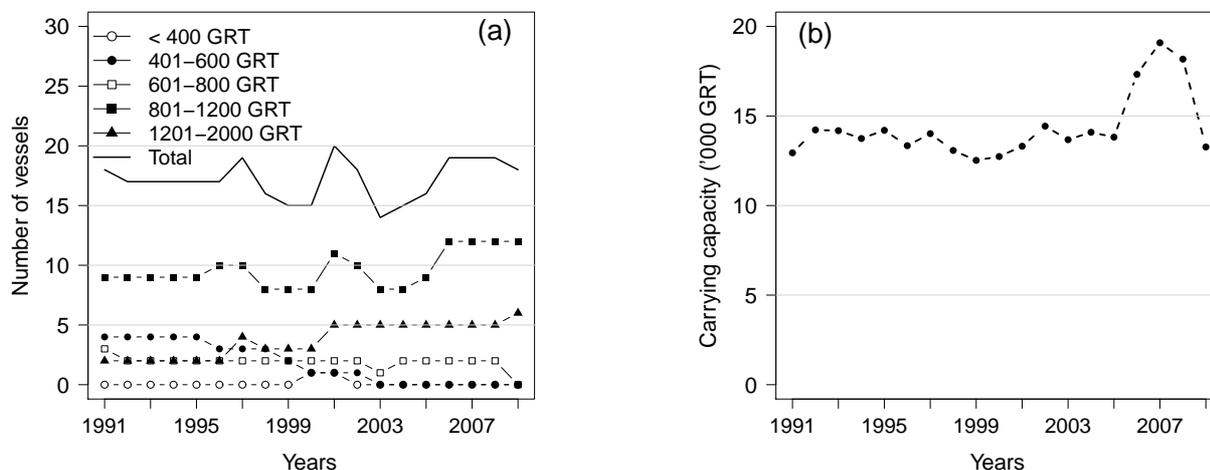

Figure 1: (a) Number of fishing vessels by GRT category operating in the Indian Ocean (b) Changes in total carrying capacity (CC) of the French fishing fleet during 1991-2009. Annual values of CC were weighted by the relative proportion of year (in months) spent in the Indian Ocean. The vessel GRT category was computed as 0.7 times the capacity expressed in m^3

4. Fishing effort

4.1. Fishing and searching days

The fishing effort expressed in fishing and searching days showed similar patterns over 1991-2009 with a decrease from 1993 to 2003 followed by a large increase during 2006-2008 (Fig. 2). Fishing effort strongly decreased in 2009 and reached the lowest values of the time period with 3,315 and 2,779 fishing and searching days, respectively. This pattern was consistent with the changes of the carrying capacity observed over the time period (Fig. 1b) due to the departure of some vessels to the Atlantic ocean (see above).
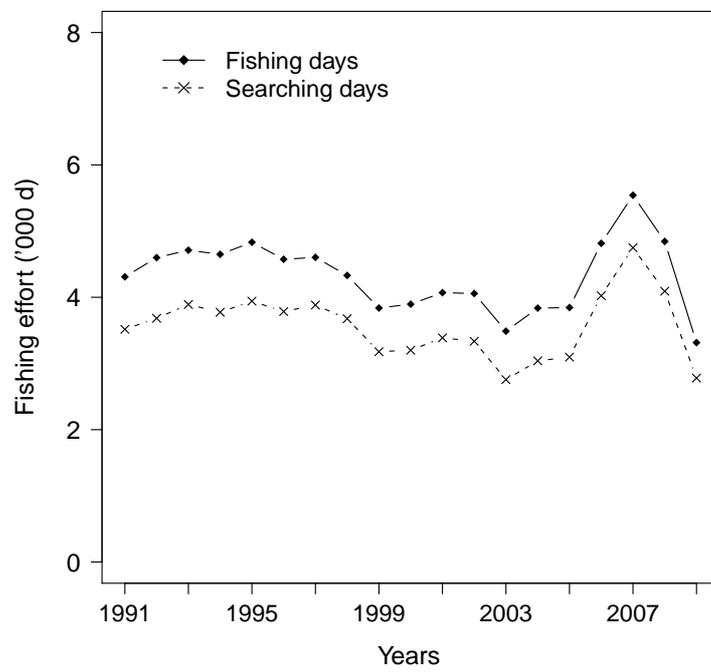

Figure 2: Annual total number of fishing and searching days for the French purse seine fleet in the Indian Ocean during 1991-2009
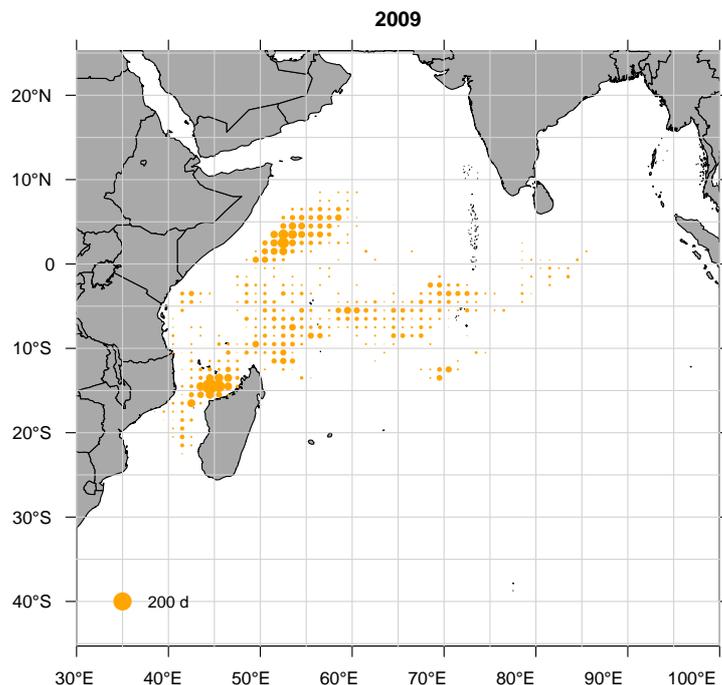

Figure 3: Spatial distribution of fishing effort (in searching days) of the French purse seine fishing fleet in 2009

The fishing effort of the French purse seine fishing fleet is mainly distributed in the western Indian Ocean, south of 10°N and north of 20°S (Fig. 3).

4.2. Fishing activities

Whatever the selection criterium applied, the number of 1-degree squares by latitude and longitude where the French purse seiners occurred showed similar patterns over the period 1991-2009, except for the final year (Fig. 4 and Table 3). The purse seine fishing grounds increased from 1991 to 1998 and then decreased to reach in the early 2000s similar levels as observed in the early 1990s. The high values of spatial occupancy in 1998 corresponded to one of the strongest warm events observed in the Indian Ocean (Murtuggude et al. 1999, Murtugudde et al. 2000) that led purse seiners fishing in the eastern zone (Ménard et al. 2007). The fishing grounds area has steadily increased since 2003 but showed a decrease in 2009 probably in relation with the influence of Somali piracy and the decrease in the number of vessels occurring in the Indian Ocean.

The total annual number of fishing sets made by the French purse seine fleet has varied around 4,000 during 1991-2009, showing a general pattern consistent with the annual variations in carrying capacity and in fishing effort (expressed in fishing or searching days) of the fleet (Table 4). The fleet showed a strong decrease in the number of sets from more than 4,500 in the late 2000s to about 3,100 in 2009. The total number of sets showed a

5
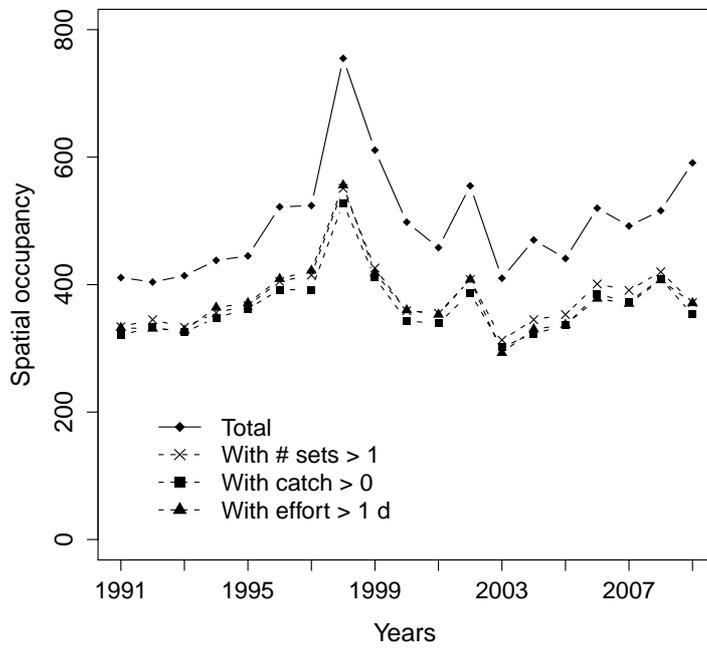

Figure 4: Annual number of 1-degree squares explored by the French purse seine fleet during 1991-2009
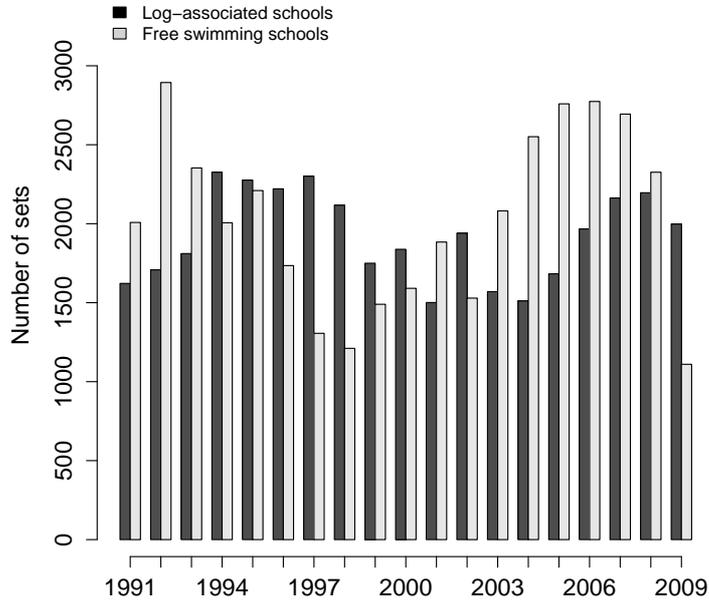

Figure 5: Annual number of fishing sets in the French purse seine fishery on log-associated and free swimming schools during 1991-2009

pattern very similar to the annual changes in the number of sets made on free swimming schools (Fig. 5). The number of sets made on log associated schools was more stable through time and in an opposite phase than sets made on free swimming schools. The percentage of log-associated over free swimming schools varied around a mean of 50% ($\pm$ SD = 10%) with log-associated fishing predominating from the mid-1990s to the early 2000s while sets made on free swimming schools were more frequent during 2003-2008. In 2009, the number of sets on free swimming schools substantially decreased from more than 2,300 to 1,110 while sets made on log-associated schools remained close to 2,000. This major decrease is related to the necessity of French purse seiners to operate in pairs for security reasons, favouring fishing on log-associated over free swimming schools. Tables 5-7 give the detail of the total number of fishing sets by set size and fishing mode.

5. Fisheries production

5.1. Catch levels

The French purse seine fishery showed strong interannual variations in the catch over 1991-2009 with a minimum of 60,000 t in 1998 and a maximum of 108,000 t during 2003-2004 (Fig. 6). Catches on log-associated schools represented about 60% of the total catch, increasing from 60% in the early 1990s to about 70% in the late 1990s, and then

Log−associated and free swimming schools
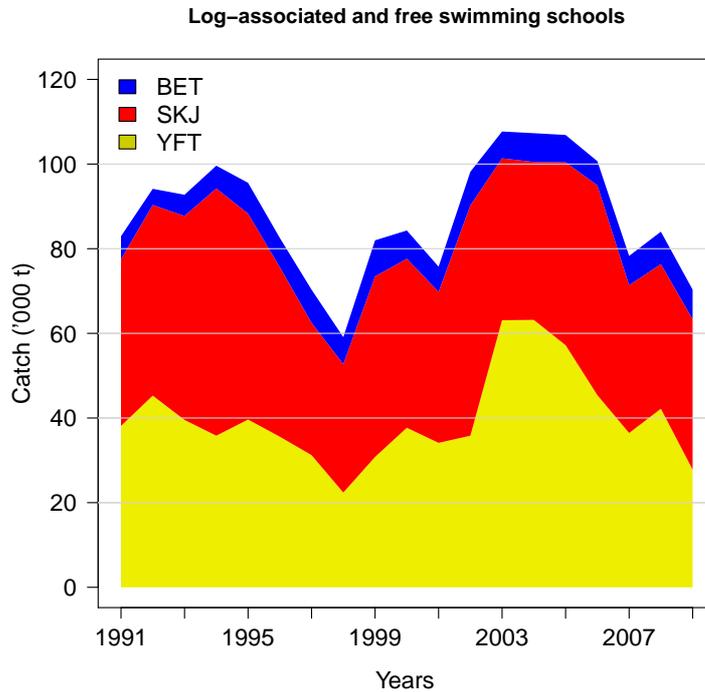

Figure 6: Catch by species of the French purse seine fishing fleet during 1991-2009

decreasing to less than 50% during 2003-2005. The percentage has increased since then to reach about 70% in 2009. Catches on log-associated schools appeared more stable than catches on free swimming schools during 1991-2009 (Fig. 7). They were largely dominated by skipjack that represented about 64% (SD ± 6.2%) of all species caught, varying from 50% to about 75% over the period (Fig. 7a). Catches of bigeye estimated through multispecies sampling varied between 5% and 14% of the total of catch on log-associated schools during 1991-2009. Catches of yellowfin on log-associated schools were stable over the period representing 27% of the catch and an annual average of about 14,000 t (SD ± 2,800 t).

Catches made on free swimming schools showed strong internannual variations in the last two decades from less than 20,000 t in the late 1990s to more than 50,000 t during 2003-2005 (Fig. 7b). The changes over time in free swimming schools catches drove the trends in the total catches of the fishery. The catches were largely dominated by yellowfin that represented more than 70% (SD ± 9%) of the catch during 1991-2009. Catches of yellowfin strongly decreased from 42,000 t in 2008 to less than 30,000 t in 2009, mainly due to the departure of 5 vessels to the Atlantic Ocean and the associated decrease in fishing sets on free swimming schools, i.e. from more than 2,300 in 2008 to about 1,100 in 2009 (Table 4).
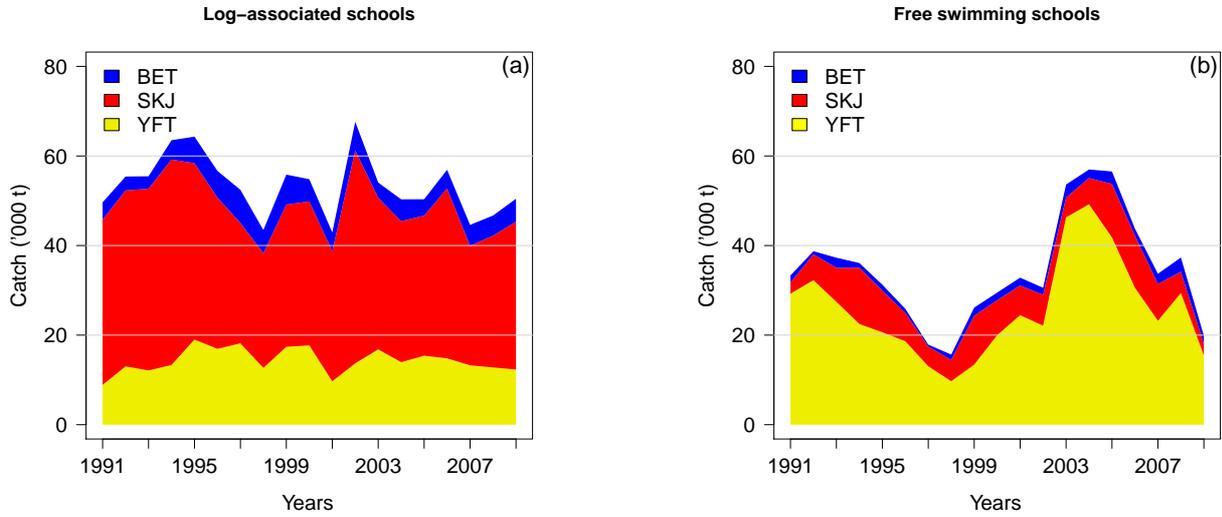

Figure 7: Catch by species of the French purse seine fishing fleet on (a) log-associated and (b) free swimming schools during 1991-2009

5.2. Spatial distribution of the catch

The spatial distribution of the catch in 2009 is highly patchy with two major fishing grounds dominated by skipjack located along the Somali coast and in the north of the Mozambique Channel; the catches dominated by yellowfin tuna being more spread along the 5°S latitude around and east of the Seychelles (Fig. 8). In 2009, few catches have been made in the areas off the coasts of Tanzania, Kenya, and the south of Somali compared to the precedent years (Fig. 9). Thanks to the boarding of military personnel aboard purse seiners to ensure their security, the fishing activities in the Somali area were made in 2009 closer to the coast than in 2008. Some catches were made in 2009 east of Maldives, south of Sri Lanka which could be linked to some environmental effects.

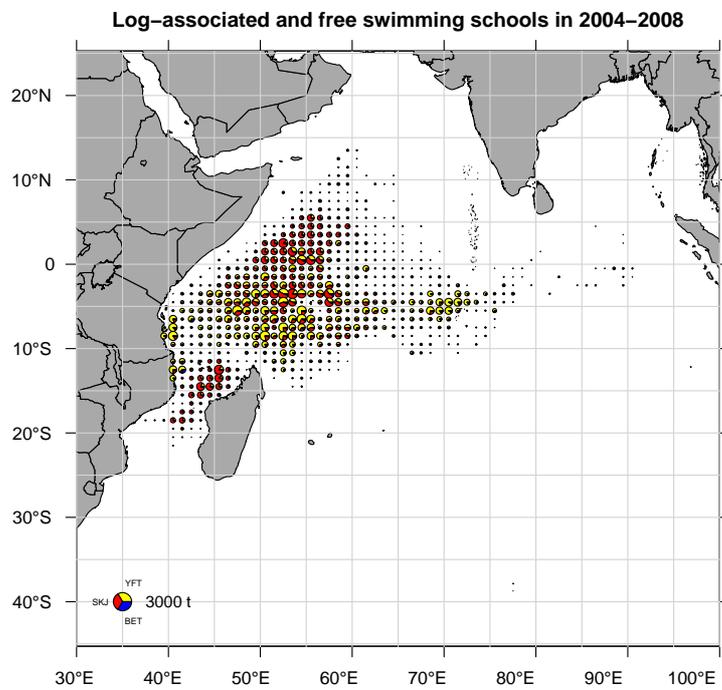

Figure 9: Spatial distribution of tuna catches of the French purse seine fishing fleet in 2004-2008

10
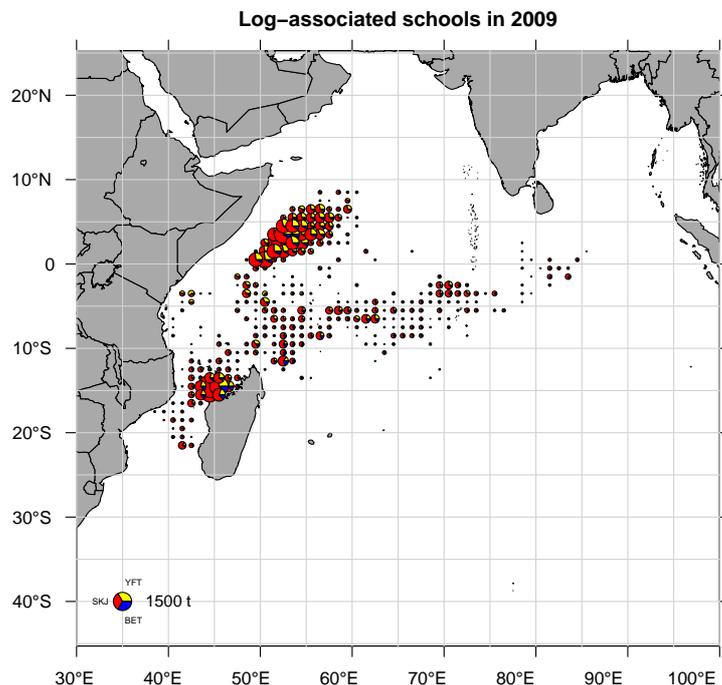

Figure 10: Spatial distribution of tuna catches of the French purse seine fishing fleet made on log-associated schools in 2009

5.3. Catch rates

The catch rates (expressed in t per fishing day) for the 3 species during 1991-2009 did not exhibit clear patterns but showed a strong interannual variability very similar to the time series of catch (Figs. 6-14). The time series of catch rates computed from data collected on log-associated school fishing for the 3 species did no show any trend over time and were characterized by high interannual variability (Fig. 15a). Catch rates were around 9.8 (CV > 20%), 4.1 (CV = 25%), and 1.4 (CV > 25%) t d^{-1} for skipjack, yellowfin, and bigeye, respectively. Catch rates of yellowfin caught on free swimming schools showed a decrease from more than 8 t d^{-1} in 1991 to less than 3 t d^{-1} in 1998. Catch rates then increased to reach levels higher than 15 t d^{-1} during 2003-2004 (Fig. 15b). Since then, catch rates have decreased to lower than average levels around 5.9 t d^{-1} in the recent years. Catch rates of skipjack on free swimming schools showed strong interannual variability around a mean value of 2 t d^{-1} and without any trend. Similarly, catch rates of bigeye did not show any clear trend over 1991-2009 and were characterized by a small mean value of 0.5 t d^{-1} (SD $\pm$ 0.24).

5.4. Size structure of the catch

The total number of fishes caught in 2009 ($\sim$ 550,000) was lower than during the period 2004-2008 ($\sim$ 740,000) while the size structure of the catch was similar for the 3 tuna species (Fig. 16). The sizes of yellowfin caught on log-associated schools showed a major

11
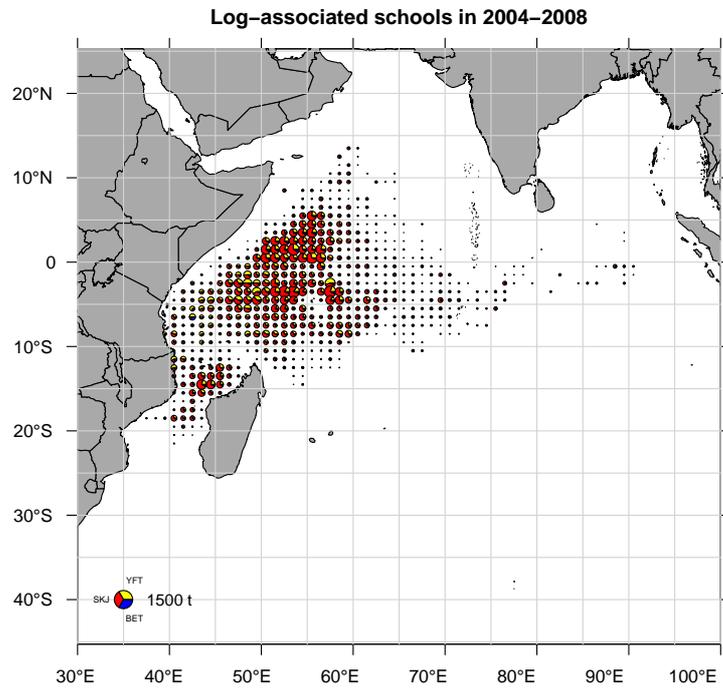

Figure 11: Spatial distribution of tuna catches of the French purse seine fishing fleet made on log-associated schools in 2004-2008
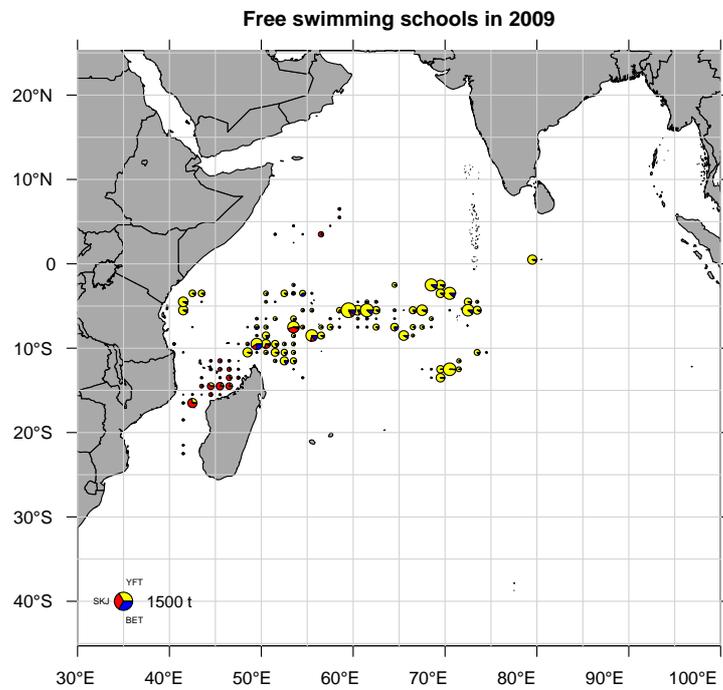

Figure 12: Spatial distribution of tuna catches of the French purse seine fishing fleet made on free swimming schools in 2009

12
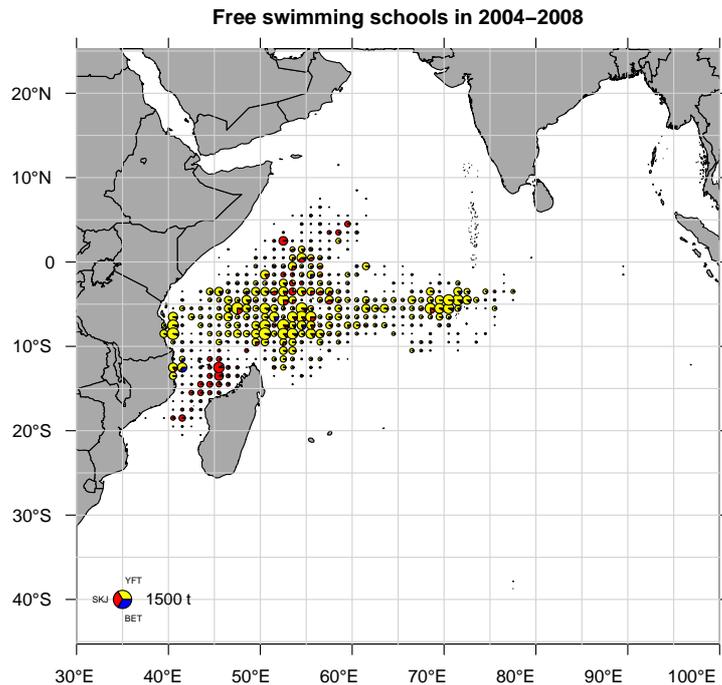

Figure 13: Spatial distribution of tuna catches of the French purse seine fishing fleet made on free swimming schools in 2004-2008

mode between 40 and 70 cm and a smaller mode around 110-120 cm. Bigeye caught on log associated schools were only juveniles fishes of median size 52 cm and the distribution was skewed to the right with a few individuals ($< 4\%$) larger than 80 cm. Skipjack showed one unique mode with sizes described by a median of 47 cm (min = 30 cm and max = 70 cm). Skipjack caught on log-associated and free swimming schools in 2009 were smaller (median sizes of 47 and 48 cm, respectively) than during the 2004-2008 period (median sizes of 48 and 52 cm, respectively).

The biomass of fish caught by size class showed very similar patterns in 2009 as observed during 2004-2008 (Fig. 17). The biomass of large yellowfin (> 100 cm) caught on log-associated and free swimming schools was lower in 2009 than for the average year 2004-2008 while it was rather similar for bigeye. The biomass of skipjack 44-50 cm long caught on log-associated schools, which represent the bulk of skipjack catch, was higher in 2009 than during 2004-2008 while there was a strong decrease in skipjack catch on free swimming schools (Table 8-10). Overall, the total catch of skipjack in 2009 was very close to the catch during 2004-2008 ($\sim$ 35,000 t) despite the strong decrease in fishing effort and was characterized by smaller individuals.

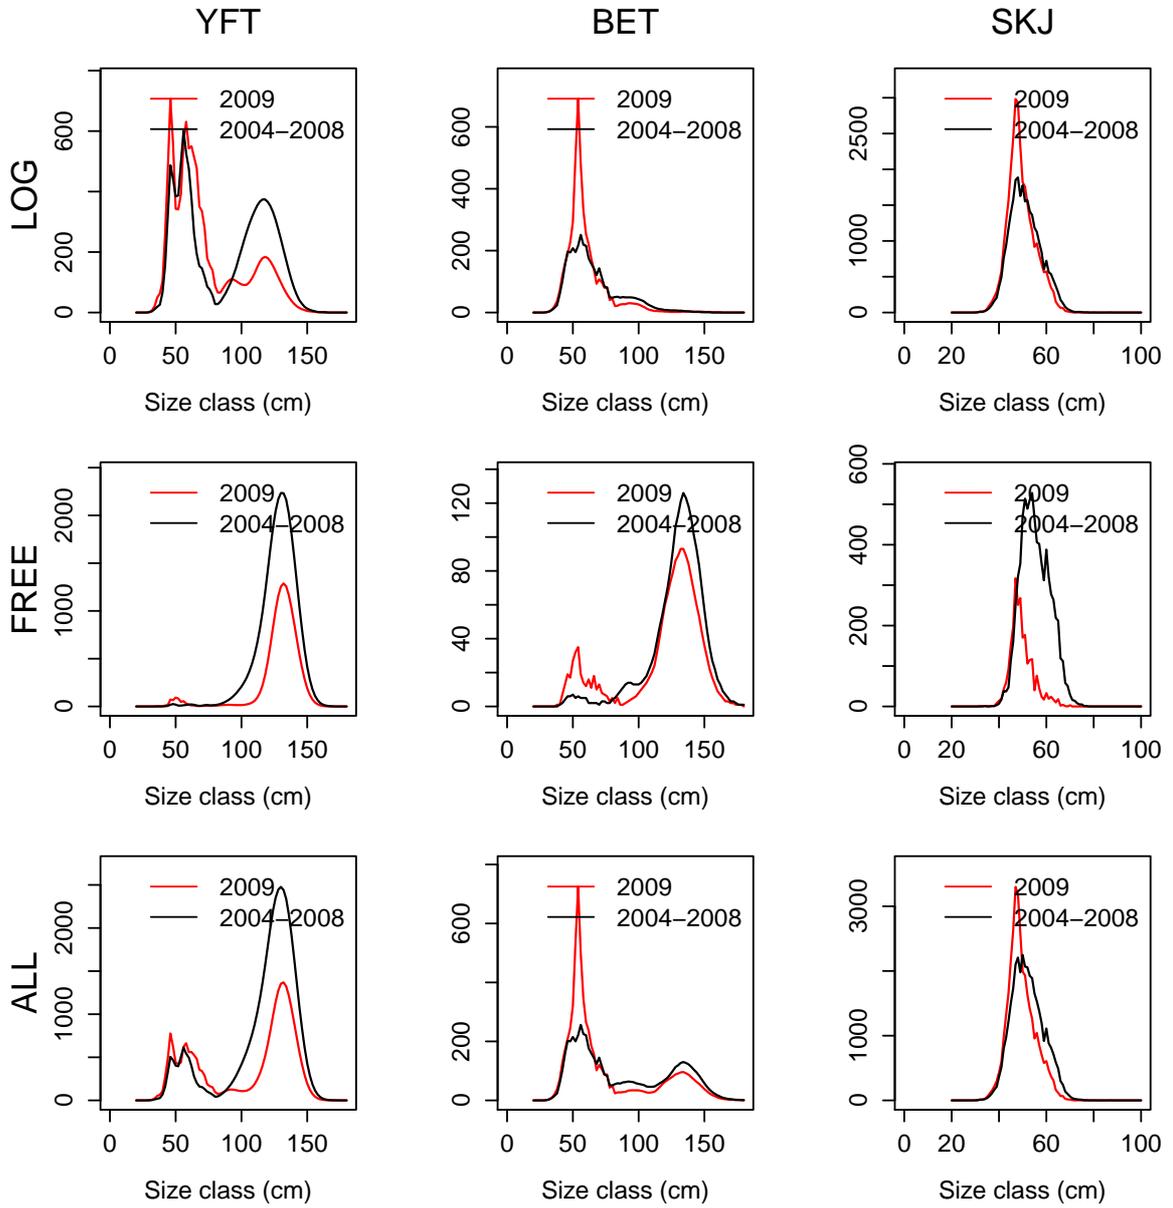

Figure 17: Total biomass (t) of fish caught by size class after extrapolation of the French purse seine fleet in 2009 and for an average year representing the period 2004-2008

5.5. Mean weight in the catch

The mean weight of the major tropical tunas in the catch highly differed between fishing modes and showed strong interannual variations during 1991-2009 (Fig. 18). The mean weight of yellowfin caught decreased from more than 37 kg in 1991 to about 15 kg in 1998-1999, before progressively increasing thereafter to reach about 40 kg in 2007-2008. The mean weight of yellowfin strongly decreased in 2009 to about 28 kg (Fig. 18a). After an initial decrease from about 10 kg in the early 1990s, the mean weight of yellowfin in the catch made on log-associated schools was stabilised from the mid-1990s to the late 2000s at around 5.8 kg (SD = ± 1.2 kg). Similarly to free swimming schools, the mean weight decreased in 2009 to reach a small value of 4.2 kg per individual caught. The time series pattern of the mean weight of yellowin for the whole fishery was mainly driven by the interannual changes in mean weight for individuals caught in free swimming schools.

The mean weight of skipjack was more stable than yellowfin during 1991-2009 and varied between a minimum of 2.3 kg in 2002 and a maximum of 3.1 in 2006 for fishes caught on log-associated schools Fig. 18b). In the recent years, the mean weight of skipjack strongly decreased from more than 3 kg in 2005-2006 to less than 2.4 kg in 2009. The mean weight of bigeye has remained stable during 1991-2009 at about 6 kg (SD ± 1 kg) for the whole fishery. It has shown strong interannual variations for individuals caught on free swimming schools with a pattern ver similar to yellowfin tuna.
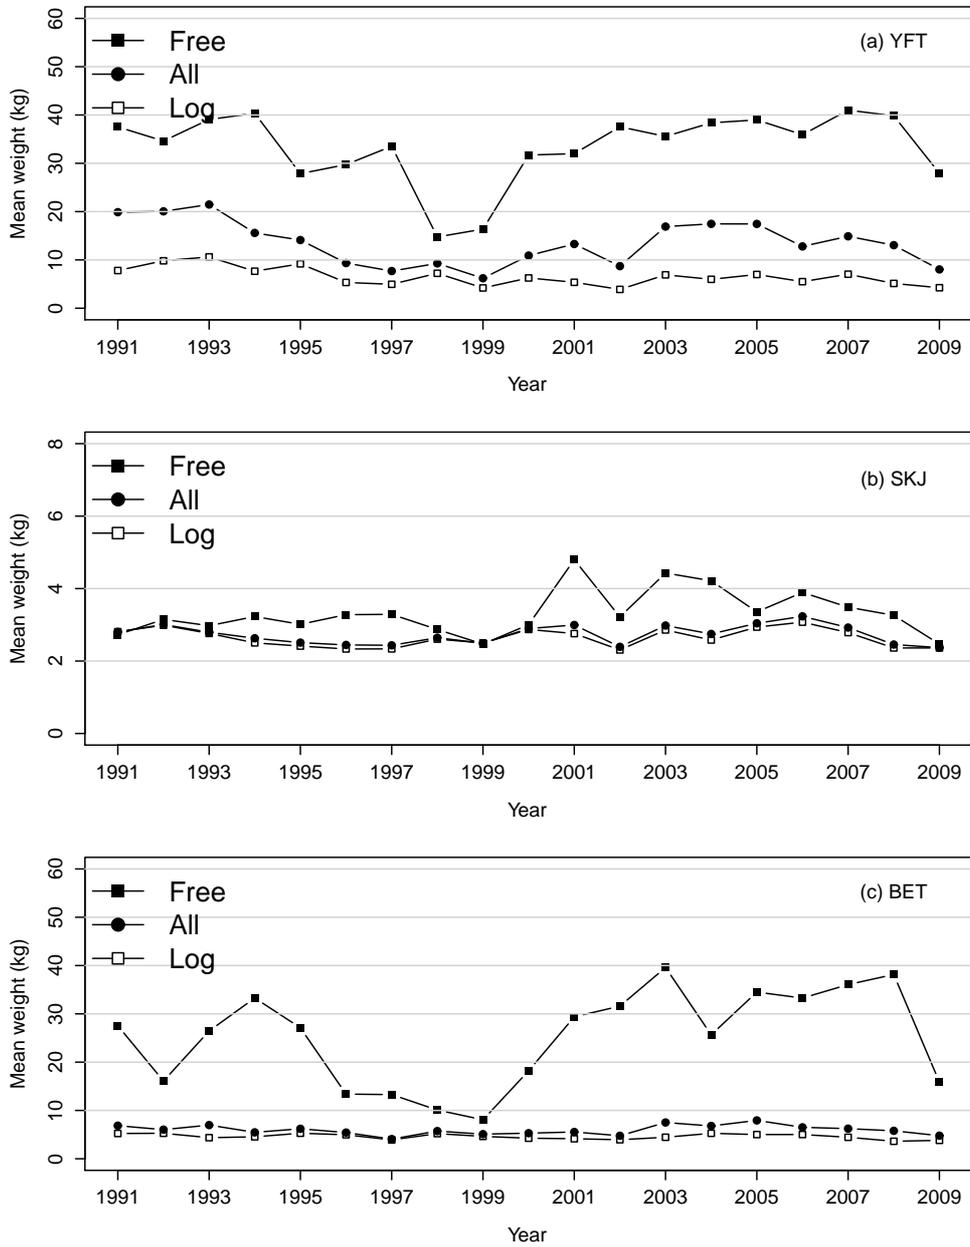

Figure 18: Annual time series of mean weight (kg) for (a) yellowfin, (b) skipjack, and (c) bigeye tuna for each fishing mode during 1991-2009
